# Design Theory for Relational Databases

#### FUNCTIONAL DEPENDENCIES DECOMPOSITIONS NORMAL FORMS

# Functional Dependencies

X ->Y is an assertion about a relation R that whenever two tuples of R agree on all the attributes of X, then they must also agree on all attributes in set Y.

- Say "X ->Y holds in R."
- Convention: ..., X, Y, Z represent sets of attributes; A, B, C,... represent single attributes.
- **Convention**: no set formers in sets of attributes, just *ABC*, rather than {*A*,*B*,*C*}.

# Splitting Right Sides of FD's

 $X \rightarrow A_1A_2...A_n$  holds for *R* exactly when each of  $X \rightarrow A_1, X \rightarrow A_2,..., X \rightarrow A_n$  hold for *R*.

Example: A->BC is equivalent to A->B and A->C.

There is no splitting rule for left sides.

We'll generally express FD's with singleton right sides.

# Example: FD's

Drinkers(name, addr, beersLiked, manf, favBeer)

Reasonable FD's to assert:

- 1. name -> addr, favBeer
  - Note this FD is the same as name -> addr and name -> favBeer.
- 2. beersLiked -> manf

#### Example: Possible Data

name	addr	beersLiked	manf	favBeer
Janeway	Voyager	Bud +	A.B.	WickedAle
Janeway	† Voyager	WickedAle	Pete's	WickedAle
Spock	Enterprise	Bud	A.B.	Bud
Because name -> addr Because name -> favBeer				
Because beersLiked -> manf				

# Keys of Relations

Set of attributes K is a *superkey* for relation R if K functionally determines all attributes of R.

K is a key for R if K is a superkey, but no proper subset of K is a superkey.

### Example: Superkey

Drinkers(name, addr, beersLiked, manf, favBeer)

Is {name, beersLiked} a superkey?

# Example: Superkey

Drinkers(name, addr, beersLiked, manf, favBeer)

{name, beersLiked} is a superkey because together these attributes determine all the other attributes.

name, beersLiked -> addr, favBeer, beersLiked, manf, favBeer

Example: Key

Is {name, beersLiked} a key?

# Example: Key

{name, beersLiked} is a key because neither {name} nor {beersLiked} is a superkey.

name doesn't -> manf; beersLiked doesn't -> addr.

There are no other keys, but lots of superkeys.

• Any superset that contains {name, beersLiked}.

# Where Do Keys Come From?

- 1. Just assert a key *K*.
  - The only FD's are  $K \rightarrow A$  for all attributes A.
- 2. Assert FD's and deduce the keys by systematic exploration.

#### More FD's

Example: "no two courses can meet in the same room at the same time" tells us: hour, room -> course.

# Inferring FD's

We are given FD's  $X_1 \rightarrow A_1$ ,  $X_2 \rightarrow A_2$ ,...,  $X_n \rightarrow A_n$ , and we want to know whether an FD  $Y \rightarrow B$  must hold in any relation that satisfies the given FD's.

• Example: If A -> B and B -> C hold, surely A -> C holds, even if we don't say so.

Important for design of good relation schemas.

# Inference Test

To test if  $Y \rightarrow B$ , start by assuming two tuples agree in all attributes of Y.

γ 0000000...0 <u>00</u>000<u>??</u>...?

# Inference Test -(2)

Use the given FD's to infer that these tuples must also agree in certain other attributes.

- If B is one of these attributes, then  $Y \rightarrow B$  is true.
- Otherwise, the two tuples, with any forced equalities, form a two-tuple relation that proves Y -> B does not follow from the given FD's.

### Example/Task

- Assume *ABC* -> *DE*, *E* -> *FG*, *G* -> *H*, *I* -> *J*.
- Is it true ABC -> G?
- Is it true ABC -> GH?
- Is it true ABC -> GHI?
- Use inference test to provide justification to your answer.

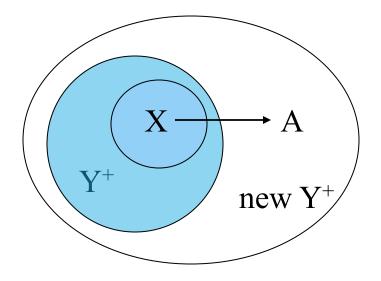

#### Closure Test

An easier way to test is to compute the *closure* of *Y*, denoted *Y*<sup>+</sup>.

Closure Y<sup>+</sup> is the set of attributes that Y functionally determines.

Basis:  $Y^+ = Y$ .

Induction: Look for an FD's left side X that is a subset of the current  $Y^+$ . If the FD is  $X \rightarrow A$ , add A to  $Y^+$ .

- Assume ABCD -> F, ABC -> D, F -> GH, I -> JGH.
- What is the closure of ABC, ABC +?

- Assume ABCD -> F, ABC -> D, F -> GH, I -> JGH.
- What is the closure of ABC, ABC +?
  - 1. Basis ABC + = ABC

- Assume ABCD -> F, ABC -> D, F -> GH, I -> JGH.
- What is the closure of ABC, ABC +?
  - 1. Basis ABC + = ABC
  - 2. ABC + = ABC + union D, since ABC is a subset of ABC + and ABC -> D

- Assume ABCD -> F, ABC -> D, F -> GH, I -> JGH.
- What is the closure of ABC, ABC +?
  - **1**. Basis  $ABC^+ = ABC$
  - 2. ABC + = ABC + union D, since ABC is a subset of ABC + and ABC -> D
  - 3. ABC + = ABC + union F, since ABCD is a subset of ABC + and ABCD -> F

- Assume ABCD -> F, ABC -> D, F -> GH, I -> JGH.
- What is the closure of ABC, ABC +?
  - **1**. Basis  $ABC^+ = ABC$
  - 2. ABC + = ABC + union D, since ABC is a subset of ABC + and ABC -> D
  - 3. ABC + = ABC + union F, since ABCD is a subset of ABC + and ABCD -> F
  - 4. ABC + = ABC + plus GH, since F is a subset of ABC + and F -> GH

*Therefore* ABC<sup>+</sup> = ABCDFGH.

Hence, for instance, ABC -> H is true but ABC -> I is not

#### Task

- Assume *AB* -> *CH*, *C* -> *D*, *HD* -> *A*, *ACH* -> *EFG*, *I* -> *A*.
- What is the closure of CH, CH +?

Is it true that CH -> G and CH -> B?.

# Finding All Implied FD's

Motivation: "normalization," the process where we break a relation schema into two or more schemas.

Example: *ABCD* with FD's *AB* ->*C*, *C* ->*D*, and *D* ->*A*.

- Assume we decompose into *ABC*, *AD*. What FD's hold in *ABC*?
- *AB* ->*C* holds but how about *C* ->*A*? Perform Inference Test OR Closure Test

# Finding All Implied FD's

Motivation: "normalization," the process where we break a relation schema into two or more schemas.

Example: *ABCD* with FD's *AB* ->*C*, *C* ->*D*, and *D* ->*A*.

- Decompose into ABC, AD. What FD's hold in ABC?
- Not only *AB* ->*C*, but also *C* ->*A*? as C+ = CDA Yes!

# Basic Idea for decomposing table

- 1. Start with given FD's and find all FD's that follow from the given FD's.
- 2. Restrict to those FD's that involve only attributes of the projected schema.

# Simple, Exponential Algorithm

- 1. For each set of attributes *X*, compute *X*<sup>+</sup>.
- 2. Finally, use only FD's involving projected attributes.

#### A Few Tricks

No need to compute the closure of the set of all attributes.

If we find  $X^+$  = all attributes, so is the closure of any superset of X.

# Example: Projecting FD's

ABC with FD's A ->B and B ->C. Project onto AC.

- *A* +=*ABC* ; yields *A* ->*B*, *A* ->*C*.
  - We do not need to compute *AB* + or *AC* + or *ABC* +.
- *B*<sup>+</sup>=*BC*; yields *B*->*C*.
- C +=C ; yields nothing.
- *BC*+=*BC*; yields nothing.

#### Example -- Continued

Resulting FD's: A ->B, A ->C, and B ->C.

Projection onto *AC* : *A* ->*C*.

• Only FD that involves a subset of {*A*,*C*}.

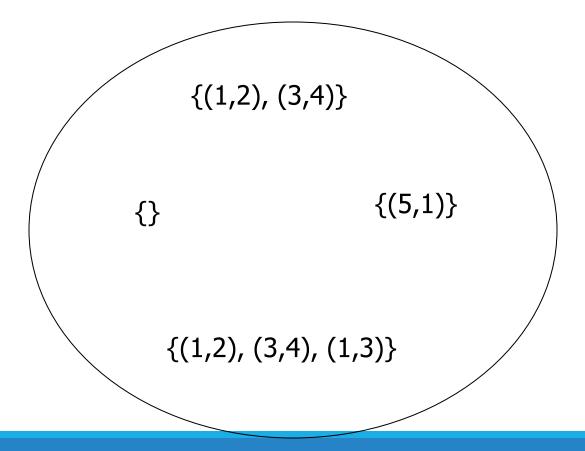

# A Geometric View of FD's

Imagine the set of all *instances* of a particular relation.

That is, all finite sets of tuples that have the proper number of components.

Each instance is a point in this space.

#### Example: R(A,B)

# An FD is a Subset of Instances

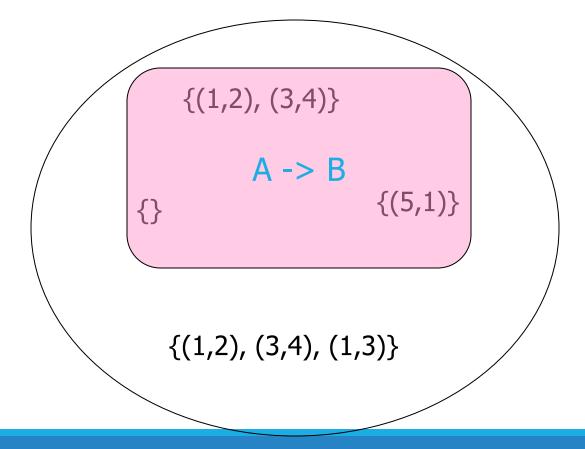

For each FD  $X \rightarrow A$  there is a subset of all instances that satisfy the FD.

We can represent an FD by a region in the space.

Trivial FD = an FD that is represented by the entire space.

• Example:  $A \rightarrow A$ .

#### Example: A -> B for R(A,B)

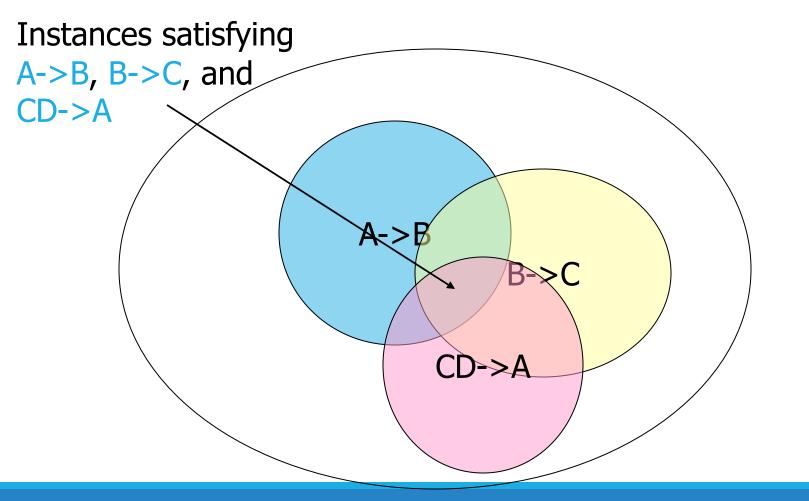

# Representing Sets of FD's

If each FD is a set of relation instances, then a collection of FD's corresponds to the intersection of those sets.

• Intersection = all instances that satisfy all of the FD's.

#### Example

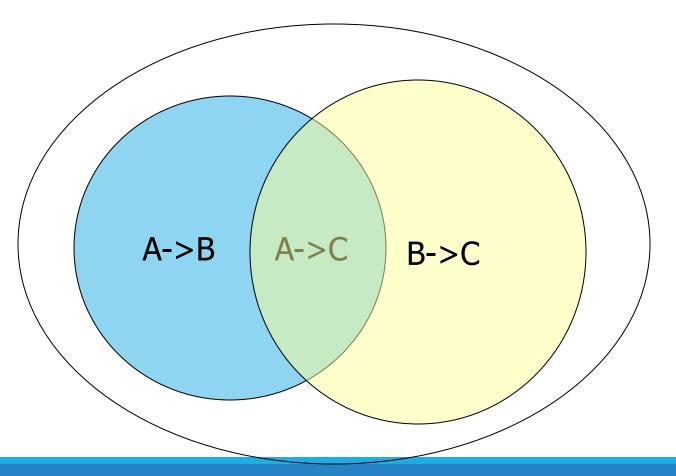

# Implication of FD's

If an FD  $Y \rightarrow B$  follows from FD's  $X_1 \rightarrow A_1, ..., X_n \rightarrow A_n$ , then the region in the space of instances for  $Y \rightarrow B$  must include the intersection of the regions for the FD's  $X_i \rightarrow A_i$ .

• That is, every instance satisfying all the FD's  $X_i \rightarrow A_i$  surely satisfies  $Y \rightarrow B$ .

### Example

# Relational Schema Design

Goal of relational schema design is to avoid anomalies and redundancy.

- Update anomaly : one occurrence of a fact is changed, but not all occurrences.
- *Deletion anomaly* : valid fact is lost when a tuple is deleted.

## Example of Bad Design

#### Drinkers(<u>name</u>, addr, <u>beersLiked</u>, manf, favBeer)

name	addr	beersLiked	manf	favBeer
Janeway	Voyager	Bud	A.B.	WickedAle
Janeway	???	WickedAle	Pete's	???
Spock	Enterprise	Bud	???	Bud

Data is redundant, because each of the ???'s can be figured out by using the FD's name -> addr favBeer and beersLiked -> manf.

#### This Bad Design Also Exhibits Anomalies

name	addr	beersLiked	manf	favBeer
Janeway	Voyager	Bud	A.B.	WickedAle
Janeway	Voyager	WickedAle	Pete's	WickedAle
Spock	Enterprise	Bud	A.B.	Bud

- Update anomaly: if Janeway is transferred to *Intrepid*, will we remember to change each of her tuples?
- Deletion anomaly: If nobody likes Bud, we lose track of the fact that Anheuser-Busch manufactures Bud.

# Boyce-Codd Normal Form

We say a relation R is in **BCNF** if whenever  $X \rightarrow Y$  is a nontrivial FD that holds in R, X is a superkey.

- *nontrivial* means Y is not contained in X.
- Remember, a *superkey* is any superset of a key

## Example

Drinkers(<u>name</u>, addr, <u>beersLiked</u>, manf, favBeer)

FD's: name->addr, favBeer, beersLiked->manf

In each FD, the left side is *not* a superkey.

Any one of these FD's shows Drinkers is not in BCNF

## Another Example

Beers(name, manf, manfAddr)

FD's: name->manf, manf->manfAddr

Only key is {name}.

name->manf does not violate BCNF because name is a superkey, but manf->manfAddr does because manf is not a superkey.

## Decomposition into BCNF

Given: relation *R* with FD's *F*.

Look among the given FD's for a BCNF violation:  $X \rightarrow Y$ .

• Compute X +

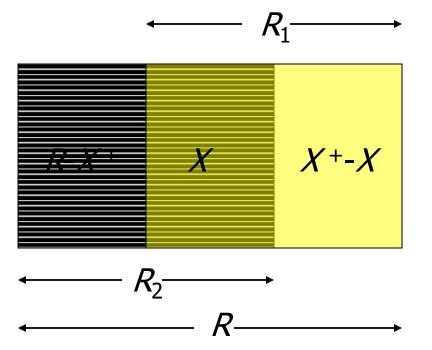

## Decompose R Using X -> Y

Replace *R* by relations with schemas:

- **1**.  $R_1 = X^+$ .
- 2.  $R_2 = R X^+ + X$ .

**Project** given FD's F onto the two new relations.

#### **Decomposition Picture**

## Example: BCNF Decomposition

Drinkers(<u>name</u>, addr, <u>beersLiked</u>, manf, favBeer)

F = name->addr, name -> favBeer, beersLiked->manf

Pick BCNF violation name->addr.

Closure of the left side: {name}<sup>+</sup> = {name, addr, favBeer}.

Decomposed relations:

- 1. Drinkers1(<u>name</u>, addr, favBeer)
- 2. Drinkers2(<u>name</u>, <u>beersLiked</u>, manf)

### Example -- Continued

We are not done; we need to check Drinkers1 and Drinkers2 for BCNF.

Projecting FD's is easy here.

For Drinkers1(<u>name</u>, addr, favBeer), relevant FD's are name->addr and name->favBeer.

• Thus, Drinkers1 is in BCNF.

## Example -- Continued

For Drinkers2(name, beersLiked, manf), one of the FDs is beersLiked->manf but beersLiked is not a superkey.

• Violation of BCNF.

beersLiked<sup>+</sup> = {beersLiked, manf}, so we decompose Drinkers2 into:

- 1. Drinkers3(beersLiked, manf)
- 2. Drinkers4(name, beersLiked)

### Example -- Concluded

The resulting decomposition of *Drinkers* :

- 1. Drinkers1(<u>name</u>, addr, favBeer)
- 2. Drinkers3(beersLiked, manf)
- 3. Drinkers4(name, beersLiked)

Notice: *Drinkers1* tells us about drinkers, *Drinkers3* tells us about beers, and *Drinkers4* tells us the relationship between drinkers and the beers they like.

# Constructing a Minimal Basis

- 1. Split right sides.
- 2. Repeatedly try to remove an FD and see if the remaining FD's are equivalent to the original.
- 3. Repeatedly try to remove an attribute from a left side and see if the resulting FD's are equivalent to the original.
